

Assessment of Biological Embodiment by Foldscope

Rushna Rais Ahmad Ansari

G.M Momin Women's College, Bhiwandi, Maharashtra.

ABSTRACT

In developing country like India, teaching science and learning needs huge investment. Resources are limited and hence the Indo-Us project by Dr. Manu Prakash inspired many young minds by developing Foldscope In 2012. Through the production of low-cost tools to community around the world, they aim to break down cost barrier between people & curiosity and excitement of scientific exploration. It can be used as an education tool to make science learning as fun. It brings Microscopy to new place. It is designed to be durable, portable, and make science more accessible to everyone. The present study evaluated the use of foldscope to observe microbes and plant specimen within KME society campus where the observation reveals the presence of beautiful creatures. Like tardigrades, amoeba, Euglena etc along with the plant tissue. Using Foldscope with smartphone documentation qualitative and quantitative were carried out at Department of Biotechnology, GM Momin Women's College, Bhiwandi during 2019-20. Viewing microbes under foldscope was delightful experience that doesn't have to cost a ton of money. It also provides new opportunities to field worker and people who want to explore beauty of nature. The extra ordinary feature of this microscope is that it can attached to Smartphone and use to capture photo and video's in real time which is hard task in other microscope on field and in laboratory at ease.

Keywords: Foldscope, microbes, curiosity, science learning, Indo-Us project.

INTRODUCTION

Invention of microscope changed the perspective of humans towards nature. Most microscopes are rather expensive and, therefore, often beyond the reach of many students and institutions. An affordable and sturdy microscope was developed by Dr. Manu Prakash and his team at Stanford University (USA) in 2012 (Cybulski et al., 2014), which can provide a magnification from 140x to 2000x with submicron resolution. This "Foldscope" microscope is made of paper and uses the principle of "Origami". Although punched only on a flat sheet of paper, it is robust enough for field study and because of its low cost; it can reach in resource-limited conditions (Neikha et al., 2020; Walling et al., 2020).

With the intend of science for all and utility of foldscope, KME society's G.M.Momin Womens college Bhiwandi in the year 2018 received the DBT grand under Indo-US project Department of Biotechnology with the motive of conducting research work, innovative teaching learning, trained and encouraged the student towards science exploration.

Here in this paper the part of work done is highlighted which discuss about the observation of various micro-flora and fauna within the vicinity of college which gives motivation to perform field study and in lab observation of beautiful microscopic world.

METHOD

Foldscupe is ready to use in three easy steps.

- First Involve assembling toldscope unit by Joining together different pieces from flat sheet provided in foldscope kit
- Second focuses on working sample.
- Third capture Image of Object using Smart phone coupled to foldscope.

Fig 1: (Assembled Foldscope)

Sample preparation:

Sampling Involves mounting a drop of specimen (water) on slide and covering it with a glass cover slip.

Slide Insertion and Focusing:

The slide is inserted within slide pocket upside down (towards yellow side). Focusing of mounted object can be adjusted in simple way by sliding paper platform with thumb and forefinger.

Viewing:

There are three methods to view the samples. First, the sample can be viewed directly through the eyes. Second, it can be viewed through the camera of mobile phones. To view a sample with a phone, attach a magnetic coupler (provided in kit) over the lens of your phone camera- by using either a double-sided ring sticker or with any other tape. Foldscope's lens has a magnification of 140x, and that magnification is multiplied by the zoom feature of the mobile phone. It is ideal for recording the movements of living specimens by using the video feature of the mobile phone. In the third method, a sample can be projected on a white screen or surface in a dark room. Projection requires a strong light source. A phone's flashlight can also be used. For this, attach a magnetic coupler over the phone's flashlight, and then bring phone's flashlight up to the aperture, on the yellow side of Foldscope. Turn on the flashlight, an image of the specimen will be visible on the screen.

RESULTS

With a keen observation of water sample and plant tissue using foldscope for the study, following images were captured and imaged through smart phone (Redmi note 7 pro).
